NORTH CAROLINA HEALTH SERVICE AREAS

PREFACE

The State Center for Health Statistics has produced triennially a major publication describing North Carolina's mortality experience for a five-year period. The 1981 <u>Leading Causes of Mortality</u>, the third major publication of this type, included statistical tables, maps, and graphs as well as an analysis for each leading cause of death in North Carolina. In the interim years, the State Center publishes supportive reports of mapped and tabular data only.

This edition of Leading Causes of Mortality is a supportive report which should be used in conjunction with the $\overline{1981}$ edition for purposes of health planning and analysis. Another report that can be used is $\overline{\underline{Detailed Mortality}}$ Statistics which provides annual counts of deaths classified according to detailed underlying causes of death and the age, race, and sex of decedents.

The tables and maps in this report show selected mortality statistics for counties, Department of Human Resources regions, Health Services Areas, and the state (see maps on preceding pages). More than a dozen of North Carolina's leading causes of mortality are depicted in these tables and maps. In addition, the site-specific cancers and total infant mortality are also tabled and mapped. Table 1 on page 4-3 describes the selected cause-of-death categories in terms of codes from the International Classification of Diseases (Ninth Revision). Altogether, the causes included in this report accounted for 86.6 percent of all North Carolina deaths during 1983.

As with previous editions, multiple conditions present at death are included in this volume. Three diseases in particular—hypertension, atherosclerosis, and diabetes—are considered associated conditions far more often than they are considered an underlying cause. Hence, Figures 29.A through 31.B display 1979-83 county rates for deaths associated with a mention of each of these diseases.

IN USING THIS VOLUME PARTICULAR ATTENTION IS CALLED TO THE SECTIONS ON INTERPRETATION OF MORTALITY RATES AND FLAGGING BIASED RATES.

I. COMPUTATION OF MORTALITY RATES

In this report, total death rates are expressed as resident deaths per 1,000 population while all cause-specific mortality rates are expressed as resident deaths per 100,000 population. All rates in Tables 1-27 use total population in the denominator, except rates for the sex-specific cancer sites, which use male or female population in the denominator. The infant mortality rates of Table 28 and Figure 28 are computed as the number of resident deaths under one year of age per 1,000 resident live births. Population bases for the rates of this report were provided by the Office of State Budget and Management in the Governor's Office.

Vital events in this report are allocated to place of residence. For deaths of inmates of long-term institutions (mental, penal, old age, orphan, nursing home, rest home, etc.), the institution is considered the usual residence provided the decedent had resided in the institution at least one year. College students and military personnel are considered residents of the college or military community.

The following definitions apply to the rates of Tables 1-27.

<u>Unadjusted</u> 5-Year <u>Death</u> <u>Rate</u>: the average annual death rate computed as average resident deaths per 1,000 or 100,000 average population. These rates permit the user knowledge of an area's status with respect to the observed incidence of mortality during the 5-year period. These rates are depicted in the Series A maps (e.g., Figures 2.A, 3.A, etc.) printed in blue.

Adjusted computed by the direct method. Also expressed as deaths per 1,000 or 100,000 population, these rates are those which would be expected if the average annual age, race, and sex composition of each county's population were the same as that estimated for the state. These rates are free of differing effects of age, race, and sex and thus permit the user knowledge of an area's status with respect to other determinants of mortality during the 5-year period. However, the user should not compare an adjusted death rate with an unadjusted death rate. Also, adjusted rates for different time periods cannot be directly compared unless they were adjusted by the same standard population. The adjusted rates are depicted in the Series B maps (e.g., Figures 2.B., 3.B., etc.) printed in red.

For the maps, a clustering routine* from the Statistical Analysis System (SAS) was used to group counties that are "most like each other" with respect to their unadjusted rate and then their adjusted rate (1). These maps show six levels of death rates, where level one is the lowest rate interval and level six the highest.

In 1983 the State Center for Health Statistics conducted an evaluation of several clustering methods. It was found that one method, called "Average Linkage Method," produced tighter clusters (i.e., clusters with smaller within-cluster variances) than the other methods examined. Consequently, we plan to use this method henceforth to cluster county rates in all SCHS publications.

II. INTERPRETATION OF MORTALITY RATES

To assess an area's relative mortality conditions during a five-year period, both the unadjusted rate and the adjusted rate can be compared to the state rate for a particular cause of death. Then, provided the area's unadjusted rate represents a relatively stable situation, viz., the rate has not fluctuated widely in recent years, the following alternative diagnoses will apply:

Relative Status Of

Unad justed Rate	Adjusted Rate	Diagnosis
Low	Low	Low mortality is not due to age, race, and sex factors; other mortality conditions are favorable.
Low	High	Low mortality is due to favorable age, race, and sex factors; other mortality conditions are unfavorable.
High	Low	High mortality is due to unfavorable age, race, and sex factors; other mortality conditions are favorable.
High	High	High mortality is not due to age, race, and sex factors; other mortality conditions are unfavorable.

In using adjusted rates, it is important that the user understand the reason for adjustment. The following hypothetical example illustrates. Here, A and B stand for population subgroups, e-g-, whites and nonwhites, males and females, etc.

	<u>C</u>	County			State	
	Population	Deaths	Death Rate*	Population	Deaths	Death Rate*
Population A Population B Total	300,000 10,000 310,000	1,000 10 1,010	333.3 100.0 325.8	500,000 800,000 1,300,000	2,500 1,000 3,500	500.0 125.0 269.2

^{*}Deaths per 100,000 population.

Compared to the state, county subgroups A and B both have lower rates, be the county as a whole (A and B combined) has a higher rate. This seeming paradoxical situation results from two factors: different proportions of A as B in the county vs. the state population and wide differences between the rate for A vs. B. In this example, it is true that the county has the higher total rate—BUT ONLY BECAUSE THE POPULATION CONTAINS A HIGH PROPORTION OF SUBGROUP

Certainly, it is important for program planners to know that the county has high rate relative to the state rate; this information is needed determining manpower and facility needs, etc. But in assessing "risk," to researcher needs to adjust for confounding factors such as age or race. To this, one multiplies each population-specific county rate by the correspondi "standard" population, sums these results, and divides by the total "standard In the above example, using the state population as the standard, to computation is:

Thus, as rates specific for A and B imply, the county's rate is lower th the state's rate after adjustment for the factor represented by A and B.

Caution!

In assessing the relative mortality conditions of a county, one should particularly aware of rates based on small numbers of deaths since, in su cases, random fluctuation in the rate may render rate comparisons risky. Treader should read very carefully the next section entitled "Flagging Bias Rates."

III. FLAGGING BIASED RATES

The age-race-sex adjusted rates in this publication that have been determined to be biased are flagged with an asterisk to suggest caution in their use. A complete description of the rationale and method for flagging biased rates can be found in the 1981 Leading Causes of Mortality. A short summary is provided below.

Any rate with a small number of events (deaths) in the numerator will have substantial random variability over time, or a large standard error. A useful rule of thumb is that any rate based on fewer than 20 events in the numerator may involve serious random error and should be used very cautiously in making comparisons or assessing trends (2). Many of the rates in this volume do have numerators smaller than 20.

In addition to the problem of a large standard error, the age-race-sex-adjusted rates in this volume may be biased due to one or more deaths in a small age-race-sex population group. One death out of an estimated population of 5, for example, would produce a death rate of 20,000 per 100,000 population. If this rate were applied to the appropriate age-race-sex group of the standard population, a very large number of expected deaths would result and the adjusted rate would be biased. In this volume an adjusted rate is flagged if:

a) applying the age-race-sex-specific rates of a county for a given cause to the standard population results in more than 25 percent of the total expected deaths being generated by one cell, and b) the denominator of the rate is also less than 50 (an average of 10 per year). Thirty out of a total of 2500 county adjusted rates in this volume are flagged by this method.

In addition to putting asterisks by those 1979-83 adjusted rates with a large bias due to an extremely high age-race-sex-specific rate, the rates have been recomputed by substituting the appropriate North Carolina age-race-sex-cause-specific rate in the problem cell. The table on the next page compares the flagged rates with the rates where the state rate has been substituted. The reader who must use one of these flagged rates is advised to use the rate in this table with the substitution instead. If the latter rate is clearly out of line with the North Carolina rate in the last column, the rate should be treated as missing data.

IV. NORTH CAROLINA MORTALITY HIGHLIGHTS

In the 1981 Leading Causes of Mortality extensive analyses of North Carolina's mortality experience were presented. That volume contained statistical tables, maps, and graphs as well as cause-specific discussions of trends, geographic patterns, risk factors, and recent research. We do not expect that the general mortality picture has changed very much in two years. Thus in this section, we will highlight 1983 unadjusted death rates for selected causes and the changes in rates from 1981 through 1983. The reader should consult the 1981 volume for a detailed discussion of each cause.

- As shown in Table 1, a total of 50,181 North Carolinians died in 1983, a rate of 8.25 deaths per 1,000 population. The 1983 rate represents a 2.4 percent increase over the 1982 rate which was 2.3 percent below the 1981 rate.
- The median age at death was 71.4 years in 1983, up from 70.7 in 1982, 70.4 in 1981, 66.4 in 1970, and 28.1 in 1914 when deaths were first centrally recorded.
- The ten leading causes of death are heart disease, cancer, cerebrovascular disease, accidents, chronic obstructive pulmonary disease, pneumonia and influenza, diabetes, suicide, atherosclerosis, and homicide.
- Of the selected causes of death shown in this volume, rates for cancer and chronic obstructive pulmonary disease increased each year from 1981 to 1983 while rates for cerebrovascular disease, chronic liver disease and cirrhosis, motor vehicle accidents, and homicides declined each year. While the two increases were not statistically significant at the .05 level, the four decreases were.
- Among the nine site-specific cancers referenced in this volume, breast, lung, and ovarian cancers showed steady unadjusted rate increases between 1981 and 1983 while pancreatic cancer showed a steady decline. The percent changes for the increasing rates were 8.4, 6.6, and 3.6 respectively while the percent decline for cancer of the pancreas was 9.4. The rates for the other site-specific cancers fluctuated between 1981 and 1983, but their 1983 rates were comparable to their 1981 or 1982 rate, or both. Among these cancers, leukemia had the largest percent change from 1982 to 1983 (declining 14.6 percent), making its 1983 rate 7.7 percent lower than the 1981 rate.
- While the steady increase in the unadjusted rate for female breast cancer occurred among both race groups, a different pattern existed with ovarian cancer. Among white females who comprised 84 percent of all ovarian cancer decedents in 1983, the ovarian cancer rate increased 22.7 percent from 1981 and 1982 but decreased 3.6 percent from 1982 and 1983. On the other hand, the rate for nonwhites

declined 51 percent from 1981 to 1982 but <u>increased</u> 30.9 percent from 1982 to 1983. However, since these rates are based on a small number of events, comparisons are risky.

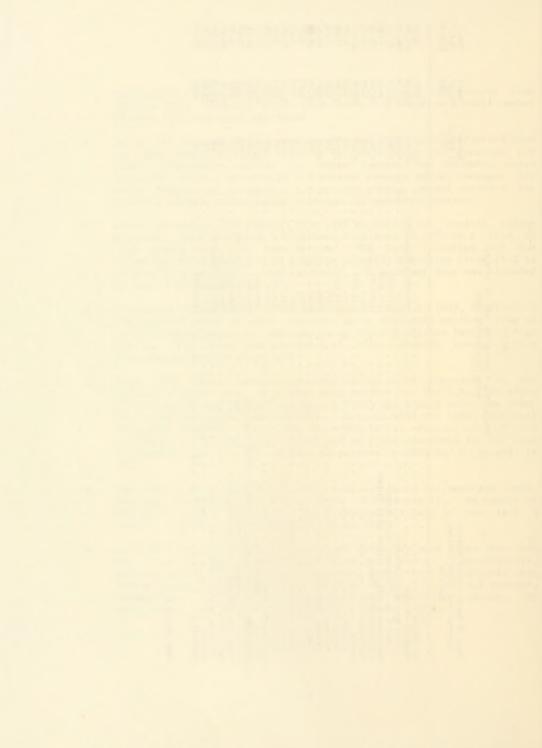

- Among the race-sex groups between 1981 and 1983, the unadjusted rate for lung cancer increased steadily for white males (4.7 percent per year), fluctuated sharply for white females and nonwhite males (although showing an overall 4.1 percent average annual increase for white females and an overall 1.9 percent average annual decrease for nonwhite males), and remained constant for nonwhite females.
- After increasing 4.0 percent from 1981 to 1982, the overall infant mortality rate declined 3.4 percent from 1982 to 1983 to a rate of 13.2 deaths per 1000 live births. The rate reduction was due primarily to a reduction in nonwhite neonatal mortality (from 14.2 in 1982 to 12.5 in 1983). Provisionally, NC's infant rate was exceeded by only 3 states in 1983 (3).
- The number of suicides, which reached a new high in 1982, declined to 748 recorded cases in 1983. Suicides among teenagers declined from 62 to 36 recorded cases but suicides among elderly persons increased from 125 to 141. With the exception of 1980, elderly suicides have increased each year since 1977.
- Since 1960 North Carolina has experienced rapid increases in the septicemia death rate, a pattern also evident for the U.S. The 1970-80 average annual percent increase (19.4%) was almost twice the 1960-70 average annual increase (10.0%). Between 1981 and 1983, the rate increased another 22 percent (from 5.0 to 6.1 deaths per 100,000 population). Approximately 74 percent of these decedents in 1983 were 65 years of age or over, up from 65 percent in 1982 and 60 percent in 1981.
- The state's motor vehicle mortality rate continued its downward trend, dropping another 6.7 percent in 1983. Unfortunately, the number of decedents under the age of 2 has increased slightly in the last 3 years (11 in 1981, 12 in 1982, and 16 in 1983).
- Certain chronic diseases are present at death far more often than they are considered the underlying cause of death. Specifically, atherosclerosis, hypertension, diabetes, and nephritis/nephrosis were listed on the death certificates of 27.6, 8.5, 7.5, and 4.9 percent, respectively, of all 1983 decedents. As underlying causes, the percentages were 1.1, 0.5, 1.7, and 1.1, respectively.

*Numbers shown here are the final underlying frequencies. They are sometimes larger than numbers shown on the clasonal due to the fact that sequence of conditions may imply an underlying cause that is not specifically mentioned on the death certificate.

æ

**Differences between these totals and the summation over causes are attributable to causes not given in the table.

In this table, a death counted only once in a condition category although several conditions within the category may have been reported or a single condition may have been recorded more than once on the death certificate. Note:

æ of between these totals and the summation over causes are attributable to causes not given in the table and to multiple counting condition if it appears in combination with more than one other condition on a certificate. *Differences

see Also, the ICD-9 codes used to count hypertension In this table, a death is counted only once in a condition category although several conditions within the category may have been reported atherosclerosis mentions are different from the codes used to count underlying cause elsewhere in this report. For further explanation single condition may have been recorded more than once on the death certificate. Multiple Conditions Present at Death: A Special Study, SCHS, 1982. Note:
